Off-Line Digital Green-Mode Quasi-Resonant PWM Controller

iWatt
Power Management Simplified Digitally™

1.0 Features

- No-load power consumption < 30mW at $230V_{AC}$ along with fast dynamic load response and short turn-on delay time in typical 12W compact adapter/charger applications

- Tight constant-voltage and constant-current regulation across line and load range

- Primary-side feedback eliminates opto-isolators and simplifies design

- Proprietary optimized 89kHz maximum PWM switching frequency with quasi-resonant operation achieves best size, efficiency and common mode noise

- User-configurable 5-level cable drop compensation provides design flexibility

- *EZ-EMI®* design enhances manufacturability

- Adaptive multi-mode PWM/PFM control improves efficiency

- No external loop compensation components required

- Complies with EPA 2.0 energy-efficiency specifications with ample margin

- Built-in single-point fault protection features: output short-circuit protection, output over-voltage protection, over-current protection and current-sense-resistor fault protection

- Dedicated pins for external over-temperature protection and over-voltage protection, with latch function available

- No audible noise over entire operating range

2.0 Description

The iW1699 is a high performance AC/DC power supply controller which uses digital control technology to build peak current mode PWM flyback power supplies. The device operates in quasi-resonant mode to provide high efficiency along with a number of key built-in protection features while minimizing the external component count, simplifying EMI design and lowering the total bill of material cost. The iW1699 removes the need for secondary feedback circuit while achieving excellent line and load regulation. It also eliminates the need for loop compensation components while maintaining stability over all operating conditions. Pulse-by-pulse waveform analysis allows for a loop response that is much faster than traditional solutions, resulting in improved dynamic load response for both one-time and repetitive load transients. The built-in power limit function enables optimized transformer design in universal off-line applications and allows for a wide input voltage range.

iWatt's innovative proprietary technology ensures that power supplies built with the iW1699 can achieve both highest average active efficiency and less than 30mW no-load power consumption, and have fast dynamic load response in a compact form factor in typical 12W and above applications. The active start-up scheme enables shortest possible start-up time without sacrificing no-load power loss.

3.0 Applications

- Compact AC/DC adapter/chargers for media tablets and smart phones
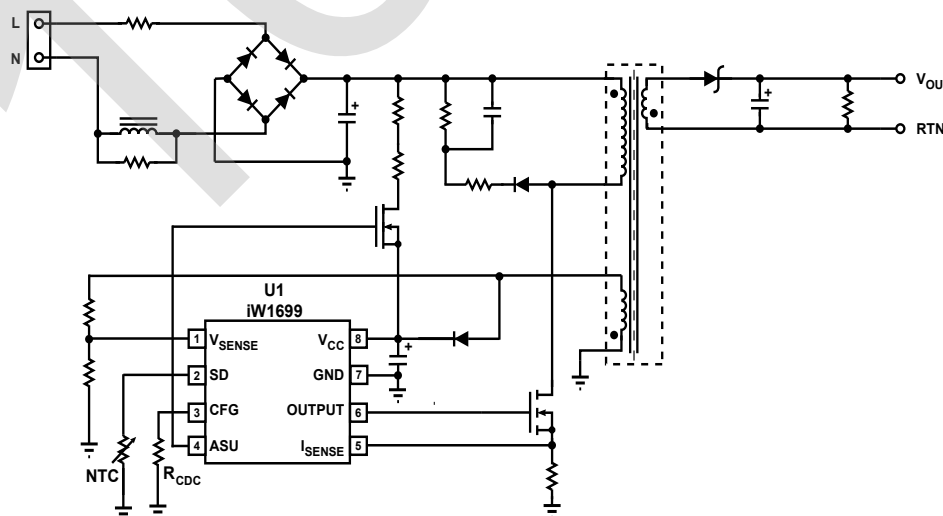

- AC/DC adapters for consumer electronics

9.0 Theory of Operation

The iW1699 is a digital controller which uses a new, proprietary primary-side control technology to eliminate the opto-isolated feedback and secondary regulation circuits required in traditional designs. This results in a low-cost solution for low power AC/DC adapters. The core PWM processor uses fixed-frequency Discontinuous Conduction Mode (DCM) operation at higher power levels and switches to variable frequency operation at light loads to maximize efficiency. Furthermore, iWatt's digital control technology enables fast dynamic response, tight output regulation, and full featured circuit protection with primary-side control.

Referring to the block diagram in Figure 8.1, the iW1699 operates in peak current mode control. The digital logic control block generates the switching on-time and off-time information based on the output voltage and current feedback signal and provides commands to dynamically control the external MOSFET gate voltage. The I_{SENSE} is an analog input configured to sense the primary current in a voltage form. In order to achieve the peak current mode control and cycle-by-cycle current limit, the V_{IPK} sets the threshold for the I_{SENSE} to compare with, and it varies in the range of 0.23V (typical) to 1.00V (typical) under different line and load conditions. The system loop is automatically compensated internally by a digital error amplifier. Adequate system phase margin and gain margin are guaranteed by design and no external analog components are required for loop compensation. The iW1699 uses an advanced digital control algorithm to reduce system design time and increase reliability.

Furthermore, accurate secondary constant current operation is achieved without the need for any secondary-side sense and control circuits.

The iW1699 uses adaptive multi-mode PWM/PFM control to dynamically change the MOSFET switching frequency for efficiency, EMI, and power consumption optimization. In addition, it achieves unique MOSFET quasi-resonant switching to further improve efficiency and reduce EMI. Built-in single-point fault protection features include over-voltage protection (OVP), output short-circuit protection (SCP), over-current protection (OCP), and I_{SENSE} fault detection. In particular, it ensures that power supplies built with the iW1699 can meet 5-star energy rating requirement and achieve fast dynamic load response in typical 12W and above compact adapter/charger applications.

iWatt's digital control scheme is specifically designed to address the challenges and trade-offs of power conversion design. This innovative technology is ideal for balancing new regulatory requirements for green mode operation with more practical design considerations such as lowest possible cost, smallest size and high performance output control.

9.1 Pin Detail

Pin 1 – V$_{SENSE}$

Sense signal input from auxiliary winding. This provides the secondary voltage feedback used for output regulation.

Pin 2 – SD

External shutdown control. If the voltage at this pin is lower than 1.2V (typical) at the beginning of start-up or lower than 1.0V (typical) during normal operation, then the IC shuts down. Leave this pin unconnected if the shutdown control is not used (Refer to Section 9.14).

Pin 3 – CFG

Used to configure external cable drop compensation (CDC) at the beginning of start-up and provide over-voltage protection during normal operation by sensing output voltage via auxiliary winding.

Pin 4 – ASU

Control signal for active startup device. This signal is pulled low after start-up is finished to cut off the active device.

Pin 5 – I$_{SENSE}$

Primary current sense. Used for cycle-by-cycle peak current control and limit.

Pin 6 – OUTPUT

Gate drive for the external power MOSFET switch.

Pin 7 – GND

Ground.

Pin 8 – V$_{CC}$

Power supply for the controller during normal operation. The controller starts up when V$_{CC}$ reaches 12V (typical) and shuts down when the V$_{CC}$ voltage drops below 5.5V (typical). A decoupling capacitor of 0.1µF or so should be connected between the V$_{CC}$ pin and GND.

9.2 Active Start-up and Soft-start

Refer to Figure 3.1 for active start-up circuit using external depletion mode NFET. Prior to start-up, the ENABLE signal is low, and the ASU pin voltage closely follows the V$_{CC}$ pin voltage, as shown in Figure 9.1. Consequently, the depletion mode NFET is turned on, allowing the start-up current to charge the V$_{CC}$ bypass capacitor. When the V$_{CC}$ bypass capacitor is charged to a voltage higher than the start-up threshold V$_{CC(ST)}$, the ENABLE signal becomes active and the iW1699 begins to perform initial OTP check (See Section 9.14), followed by CDC configuration (See Section 9.12). Afterwards, the iW1699 commences soft-start function. During this start-up process an adaptive soft-start control algorithm is applied, where the initial output pulses are small and gradually get larger until the full pulse width is achieved. The peak current is limited cycle by cycle by the I$_{PEAK}$ comparator. If at any time the V$_{CC}$ voltage drops below under-voltage lockout (UVLO) threshold V$_{CC(UVL)}$ then the iW1699 goes to shutdown. At this time ENABLE signal becomes low and the V$_{CC}$ capacitor begins to charge up again towards the start-up threshold to initiate a new soft-start process.

While the ENABLE signal initiates the soft-start process, it also pulls down the ASU pin voltage at the same time, which turns off the depletion NFET, thus minimizing the no-load standby power consumption.

In applications where active start-up is not needed, the start-up resistor can be directly connected to the V$_{CC}$ pin without using the active start-up device, and the ASU pin can be left unconnected. Refer to Figure 3.2 for the application circuit.

9.3 Understanding Primary Feedback

Figure 9.2 illustrates a simplified flyback converter. When the switch Q1 conducts during $t_{ON}(t)$, the current $i_g(t)$ is directly drawn from rectified sinusoid $v_g(t)$. The energy $E_g(t)$ is stored in the magnetizing inductance L_M. The rectifying diode D1

is reverse biased and the load current I_O is supplied by the secondary capacitor C_O. When Q1 turns off, D1 conducts and the stored energy $E_g(t)$ is delivered to the output.

Figure 9.2: Simplified Flyback Converter

In order to tightly regulate the output voltage, the information about the output voltage and load current need to be accurately sensed. In the DCM flyback converter, this information can be read via the auxiliary winding or the primary magnetizing inductance (L_M). During the Q1 on-time, the load current is supplied from the output filter capacitor C_O. The voltage across L_M is $v_g(t)$, assuming the voltage dropped across Q1 is zero. The current in Q1 ramps up linearly at a rate of:

$$\frac{di_g(t)}{dt} = \frac{v_g(t)}{L_M}$$

(9.1)

At the end of on-time, the current has ramped up to:

$$i_{g\_peak}(t) = \frac{v_g(t) \times t_{ON}}{L_M}$$

(9.2)

This current represents a stored energy of:

$$E_g = \frac{L_M}{2} \times i_{g\_peak}(t)^2$$

(9.3)

When Q1 turns off at t_O, $i_g(t)$ in L_M forces a reversal of polarities on all windings. Ignoring the communication-time caused by the leakage inductance L_K at the instant of turn-off t_O, the primary current transfers to the secondary at a peak amplitude of:

$$i_d(t) = \frac{N_P}{N_S} \times i_{g\_peak}(t)$$

(9.4)

Assuming the secondary winding is master, and the auxiliary winding is slave,

Figure 9.3: Auxiliary Voltage Waveforms

The auxiliary voltage is given by:

$$V_{AUX} = \frac{N_{AUX}}{N_S}(V_O + \Delta V)$$

(9.5)

and reflects the output voltage as shown in Figure 9.3.

The voltage at the load differs from the secondary voltage by a diode drop and IR losses. Thus, if the secondary voltage is always read at a constant secondary current, the difference between the output voltage and the secondary voltage is a fixed ΔV. Furthermore, if the voltage can be read when the secondary current is small, ΔV is also small. With the iW1699, ΔV can be ignored.

The real-time waveform analyzer in the iW1699 reads this information cycle by cycle. The part then generates a feedback voltage V_{FB}. The V_{FB} signal precisely represents the output voltage under most conditions and is used to regulate the output voltage.

9.4 Constant Voltage Operation

After soft-start has been completed, the digital control block measures the output conditions. It determines output power levels and adjusts the control system according to a light load or heavy load. If this is in the normal range, the device operates in the Constant Voltage (CV) mode, and changes the pulse width (t_{ON}) and off time (T_{OFF}) in order to meet the output voltage regulation requirements.

If no voltage is detected on V_{SENSE} it is assumed that the auxiliary winding of the transformer is either open or shorted and the iW1699 shuts down.

9.5 Constant Current Operation

The constant current (CC) mode is useful in battery charging applications. During this mode of operation the iW1699 regulates the output current at a constant level regardless of the output voltage, while avoiding continuous conduction mode.

To achieve this regulation the iW1699 senses the load current indirectly through the primary current. The primary current is detected by the I_{SENSE} pin through a resistor from the MOSFET source to ground.

The iW1699 also provides a product option to disable the CC mode operation. If the power supply enters into the CC mode during normal operation, this product option shuts down the power supply. This feature serves as an over-load protection and can be used in certain adapter applications.

Figure 9.4: Power Envelope

9.6 Multi-Mode PWM/PFM Control and

Quasi-Resonant Switching

The iW1699 uses a proprietary adaptive multi-mode PWM / PFM control to dramatically improve the light-load efficiency and thus the overall average efficiency.

During the constant voltage (CV) operation, the iW1699 normally operates in a pulse-width-modulation (PWM) mode during heavy load conditions. In the PWM mode, the switching frequency keeps around constant. As the output load I_{OUT} is reduced, the on-time t_{ON} is decreased, and the controller adaptively transitions to a pulse-frequency-modulation (PFM) mode. During the PFM mode, the MOSFET is turned on for

a set duration under a given instantaneous rectified AC input voltage, but its off time is modulated by the load current. With a decreasing load current, the off-time increases and thus the switching frequency decreases.

When the switching frequency approaches to human ear audio band, the iW1699 transitions to a second level of PWM mode, namely Deep PWM mode (DPWM). During the DPWM mode, the switching frequency keeps around 25kHz in order to avoid audible noise. As the load current is further reduced, the iW1699 transitions to a second level of PFM mode, namely Deep PFM mode (DPFM), which can reduce the switching frequency to a very low level. Although the switching frequency drops across the audible frequency range during the DPFM mode, the output current in the power converter has reduced to an insignificant level in the DPWM mode before transitioning to the DPFM mode. Therefore, the power converter practically produces no audible noise, while achieving high efficiency across varying load conditions.

As the load current reduces to very low or no-load condition, the iW1699 transitions from the DPFM to the third level of PWM mode, namely Deep-Deep PWM mode (DDPWM), where the switching frequency is fixed at around 1.8kHz.

The iW1699 also incorporates a unique proprietary quasi-resonant switching scheme that achieves valley-mode turn on for every PWM/PFM switching cycle, during all PFM and PWM modes and in both CV and CC operations. This unique feature greatly reduces the switching loss and dv/dt across the entire operating range of the power supply. Due to the nature of quasi-resonant switching, the actual switching frequency can vary slightly cycle by cycle, providing the additional benefit of reducing EMI. Together these innovative digital control architecture and algorithms enable the iW1699 to achieve highest overall efficiency and lowest EMI, without causing audible noise over entire operating range.

9.7 Less Than 30 mW No-Load Power with

Fast Load Transient Response

The iW1699 features a distinctive DDPWM control at no-load conditions to help achieve ultra-low no-load power consumption (< 30mW for typical 12W and above applications) and meanwhile to ensure fast dynamic load response. The power supply system designs including the pre-load resistor selection should ensure the power supply can operate in the DDPWM mode at the steady-state no-load condition. If the pre-load resistor is too small, the no-load power consumption increases; on the other hand, if it is too large, the output voltage may increase and even cause over-voltage since the switching frequency is fixed at

around 1.8kHz. For typical designs, the pre-load resistor is in the range of 3kΩ to 5kΩ.

Aside from the appropriate use of pre-load resistor, the iW1699 enjoys a few other features to bring down no-load power consumption as well. First, the iW1699 implements an intelligent low-power management technique that achieves ultra-low chip operating current at the no-load, typically less than 350µA. Second, a low UVLO threshold of 5.5V (typical) enables the power supply system design to have a low V_{CC} voltage at the no-load operation in order to minimize the no-load power. In addition, the active start-up scheme with depletion mode NFET eliminates the start-up resistor power consumption after the ENABLE signal becomes active. All together these features ensure lowest system cost power supplies built with the iW1699 can achieve less than 30mW no-load power consumption at $230V_{AC}$ input, and very tight constant voltage and constant current regulation over the entire operating range in typical 12 W and above compact adapter/charger applications.

While achieving ultra-low no-load power consumption, the iW1699 implements innovative proprietary digital control technology to intelligently detect any load transient events, and achieve fast dynamic load response for both one-time and repetitive load transients. In particular, for load transients that are demanded in some applications from no load to full load, the iW1699 can still maintain a fast enough response to meet the most stringent requirements, with the no-load operating frequency designed at around 1.8kHz.

9.8 Variable Frequency Operation Mode

At each of the switching cycles, the falling edge of V_{SENSE} is checked. If the falling edge of V_{SENSE} is not detected, the off-time is extended until the falling edge of V_{SENSE} is detected. The maximum allowed transformer reset time is 110µs. When the transformer reset time reaches 110µs, the iW1699 shuts off.

9.9 Internal Loop Compensation

The iW1699 incorporates an internal Digital Error Amplifier with no requirement for external loop compensation. For a typical power supply design, the loop stability is guaranteed to provide at least 45 degrees of phase margin and -20dB of gain margin.

9.10 Voltage Protection Features

The secondary maximum output DC voltage is limited by the iW1699. When the V_{SENSE} signal exceeds the output OVP

threshold at point 1 indicated in Figure 9.3 the iW1699 shuts down.

For this V_{SENSE}-based OVP, latch function is available by product options given in Section 11.0.

The iW1699 protects against input line under-voltage by setting a maximum t_{ON} time. Since output power is proportional to the squared $V_{IN} t_{ON}$ product, then for a given output power, as V_{IN} decreases the t_{ON} increases. Thus by knowing when the maximum t_{ON} time occurs the iW1699 detects that the minimum V_{IN} is reached, and shuts down. The maximum t_{ON} limit is set to 13.8µs. Also, the iW1699 monitors the voltage on the V_{CC} pin and when the voltage on this pin is below UVLO threshold the IC shuts down immediately.

When any of these faults are met the IC remains biased to discharge the V_{CC} supply. Once V_{CC} drops below UVLO threshold, the controller resets itself and then initiates a new soft-start cycle. The controller continues attempting start-up until the fault condition is removed. For the latched OVP version, the controller can only start-up when the fault is removed and input is unplugged to allow V_{CC} to drop 1.0V below UVLO threshold.

9.11 PCL, OCP and SRS Protection

Peak-current limit (PCL), over-current protection (OCP) and sense-resistor-short protection (SRSP) are features built-in to the iW1699. With the I_{SENSE} pin the iW1699 is able to monitor the peak primary current. This allows for cycle-by-cycle peak current control and limit. When the peak primary current multiplied by the I_{SENSE} resistor is greater than 1.15V, over-current is detected and the IC immediately turns off the gate driver until the next cycle. The output driver sends out a switching pulse in the next cycle, and the switching pulse continues if the OCP threshold is not reached; or, the switching pulse turns off again if the OCP threshold is reached. If the OCP occurs for several consecutive switching cycles, the iW1699 shuts down.

If the I_{SENSE} resistor is shorted there is a potential danger that over-current condition may not be detected. Thus, the IC is designed to detect this sense-resistor-short fault after start-up and shut down immediately. The V_{CC} is discharged since the IC remains biased. Once V_{CC} drops below the UVLO threshold, the controller resets itself and then initiates a new soft-start cycle. The controller continues attempting to startup, but does not fully start-up until the fault condition is removed.

9.12 CDC Configuration

The iW1699 incorporates an innovative approach to allow users to configure cable drop compensation (CDC) externally. This configuration is only performed once. It is completed after the initial OTP check but before the soft-start commences. During the CDC configuration, the internal digital control block senses the external resistance value between the CFG pin and ground, and then sets a corresponding CDC level to allow the device to compensate for IR drop in the secondary circuitry during normal operation.

Figure 3.1 shows a simple circuit to set CDC level by connecting a resistor, R_{CDC}, from the CFG pin to ground. The iW1699 provides five levels of CDC configurations: 0, 75mV, 150mV, 300mV, and 450 mV. Table 9.1 below shows the resistance range for each of the five CDC levels. In practice, it is recommended to select resistance in the middle of the range wherever possible.

The "Cable Comp" specified in Table 9.1 refers to the voltage increment at PCB end from no-load to full-load conditions in the CV mode, with the assumption that the secondary diode voltage drop can be ignored at the point when the secondary voltage is sensed. Also, the "Cable Comp" is specified based on the nominal output voltage of 5V. For different output voltage, the actual voltage increment needs to be scaled accordingly.

To calculate the amount of cable compensation needed, take the resistance of the cable and connector and multiply by the maximum output current.

For each of the CDC levels, the internal V_{SENSE}-based OVP thresholds are different. Table 9.1 also lists the typical OVP thresholds for each CDC level.

9.13 External CFG-Based OVP

In the iW1699, the CFG pin can also be used to provide the external over-voltage protection (OVP) besides fulfilling the CDC configuration. This external CFG-based OVP serves as a supplemental or extra protection in addition to the V_{SENSE}-based OVP. The circuit implementation can be found in Figure 9.5, where two resistors R1 and R2 form a voltage divider to sense output voltage via auxiliary winding, with the tapping point connected to the CFG pin. During the CDC configuration the iW1699 does not send out any drive signal at OUTPUT pin, and the switch Q1 remains in off-state. The resistors R1 and R2 are essentially connected in parallel since the bias winding is virtually shorted. Consequently, the paralleled resistance of R1 and R2 sets the CDC level. Meanwhile, during normal operation, the CFG pin reflects output voltage in real-time, in the similar fashion as the V_{SENSE} does at point 1 in Figure 9.3. The ratio of R1 to R2 sets the external OVP threshold.

The resistance values for the resistor divider, R1 and R2, can be derived as follows.

First, for the given CDC level, the paralleled resistance of R1 and R2 should be within the range listed in Table 9.1:

$$R_{CDC} = \frac{R_1 \times R_2}{R_1 + R_2} \qquad (9.6)$$

Second, during normal operation the voltage divider, R1 and R2, sets the desired OVP threshold:

$$\left(\frac{N_{AUX}}{N_{SEC}}\right) \times V_{OVP} \times \left(\frac{R_2}{R_2 + R_1}\right) >= V_{SD-TH(R)} \qquad (9.7)$$

where N_{AUX} is the number of turns for the bias winding, N_{SEC} is the number of turns for the secondary winding, V_{OVP} is

the desired OVP tripping point, and $V_{SD-TH(R)}$ is the internal comparator threshold (1.015V typically) for OVP detection.

The combination of Equations (9.6) and (9.7) leads to

$$R_1 = \left(\frac{N_{AUX}}{N_{SEC}}\right) \times R_{CDC} \times \left(\frac{V_{OVP}}{V_{SD-TH(R)}}\right)$$

$$(9.8)$$

$$R_2 = \left(\frac{R_1}{R_1 - R_{CDC}}\right) \times R_{CDC}$$

It is recommended the R_{CDC} value is taken as the median value of the resistance range as given in Table 9.1, and R1 and R2 can then be readily derived from Equation (9.8).

It should be noted when the CFG pin is used to provide external OVP, an additional constraint is applied to the resistance range given in Table 9.1. Since for the OVP configuration in Figure 9.5, a large negative voltage may occur to the auxiliary winding (V_x in Figure 9.5) during the switch on-time, which can cause a negative current flowing out of the CFG pin. Care needs to be taken to ensure R1 and R2 are large enough, so that the resulting negative current is less than the maximum allowed current, specified in Section 5.0.

9.14 External OTP

The iW1699 can be configured to provide external over-temperature protection (OTP) by connecting a Negative-Temperature-Coefficient (NTC) resistor from SD pin to GND. Internally, a 100µA current source is injected to the SD pin, which generates a voltage proportional to the NTC resistance. At high ambient temperature, the NTC

resistance becomes low, which results in a low voltage at the SD pin. If the SD pin voltage drops below an internally-set threshold, then the OTP is triggered, and the iW1699 shuts down.

In the iW1699, the external OTP has a built-in hysteresis by having two thresholds. Before start-up, the OTP is triggered if the SD pin voltage is less than 1.2V; otherwise the device begins the CDC configuration (See Section 9.12), then followed by a normal soft-start process. During normal operation, the OTP threshold is switched to 1.0V, and the device only shuts down when the SD pin voltage is less than 1.0V.

During normal operation, the external OVP and OTP detections alternate every eight cycles. During the eight-cycle window of OVP detection, the voltage at the CFG pin is fed into the internal comparator's non-inverting input. If the voltage of this pin is above 1.015V at the instant corresponding to point 1 indicated in Figure 9.3 for consecutive several cycles, then OVP is triggered. Contrarily, during the external OTP detection window, if the voltage at SD pin is below 1.0V for consecutive several cycles, then the OTP is triggered, and the device shuts down.

The SD pin and CFG pin can be configured to provide different types of applications. Figure 9.6 shows four basic configurations:

In Scheme (a), the CFG pin is directly connected to ground, which sets CDC level to be 1 (i.e. no CDC). On the other side, leaving the SD pin unconnected disables the OTP function.

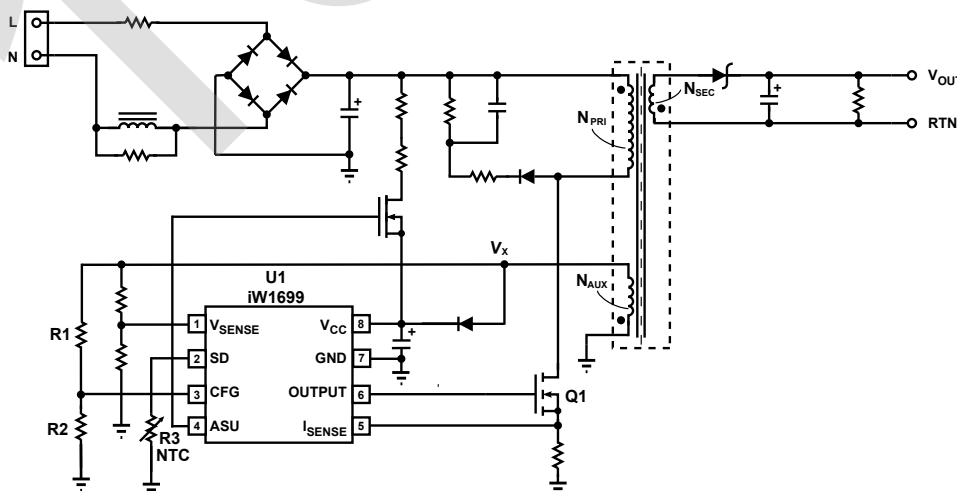

Figure 9.5: Typical Application Circuit with CDC, OVP and OTP Implemented

In Scheme (b), CDC is set to level 1, as in Scheme (a) by grounding the CFG pin. An NTC resistor in paralleled with a capacitor enables the external OTP protection. Note this capacitor is only for decoupling purpose. Its capacitance needs to be less than 47 pF, otherwise the voltage at this pin can be delayed too much, causing unwanted behaviors.

In Scheme (c), a resistor from the CFG pin to ground allows to set the desired CDC level. Similarly, the NTC resistor enables the external OTP, as in Scheme (b).

In Scheme (d), the connections to the CFG and the SD pins are complete as in Figure 9.5, allowing for any level of CDC configuration, and meanwhile enabling the external OTP and OVP.

b) OTP only, No CDC, NO OVP

c) CDC and OTP, No OVP

9.15 Latch and Release

In the iW1699, both OTP and OVP (including V_{SENSE}-based and the external CFG-based OVP) can be latched whereby the iW1699 does not attempt to start again even with the fault cleared. In the latch state, the controller recycles itself by periodically ramping V_{CC} up and down between $V_{CC(ST)}$ and $V_{CC(UVL)}$, and the controller does not start up, provided the input stays connected to the AC source. To get out of the latch state, unplugging the input from the AC source is required, so that the V_{CC} is allowed to drop 1.0V below $V_{CC(UVL)}$ to release the latch.

For a fast release, V_{CC} capacitor can be charged directly from the AC source before the diode-bridge rectifier instead of the bulk capacitor. In this way, when the input is unplugged, the V_{CC} capacitor is immediately cut off from the bulk capacitor, allowing for much faster discharging to release the latch, and initiate a normal start-up thereafter.

Compliant to JEDEC Standard MS12F

Controlling dimensions are in inches; millimeter dimensions are for reference only

This product is RoHS compliant and Halide free.

Soldering Temperature Resistance:
      [a] Package is IPC/JEDEC Std 020D Moisture Sensitivity Level 1
      [b] Package exceeds JEDEC Std No. 22-A111 for Solder Immersion Resistance; package can withstand
          10 s immersion < 270˚C

Dimension D does not include mold flash, protrusions or gate burrs. Mold flash, protrusions or gate burrs shall not exceed 0.15 mm per end. Dimension E1 does not include interlead flash or protrusion. Interlead flash or protrusion shall not exceed 0.25 mm per side.

The package top may be smaller than the package bottom. Dimensions D and E1 are determined at the outermost extremes of the plastic bocy exclusive of mold flash, tie bar burrs, gate burrs and interlead flash, but including any mismatch between the top and bottom of the plastic body.
